

Example 1 Find the image of $\triangle ABC$ under the expansion $D_{O, 2}$.

Solution $D_{O, 2}: \triangle ABC \rightarrow \triangle A'B'C'$

$$OA' = 2 \cdot OA$$

$$OB' = 2 \cdot OB$$

$$OC' = 2 \cdot OC$$

Example 2 Find the image of $\triangle RST$ under the contraction $D_{O, \frac{2}{3}}$.

Solution $D_{O, \frac{2}{3}}: \triangle RST \rightarrow \triangle R'S'T'$

$$OR' = \frac{2}{3} \cdot OR$$

$$OS' = \frac{2}{3} \cdot OS$$

$$OT' = \frac{2}{3} \cdot OT$$

In the examples above, can you prove that the two triangles are similar? How are the areas of each pair of triangles related?

Example 3 Find the image of figure F under the contraction $D_{O, -\frac{1}{2}}$.

Solution $D_{O, -\frac{1}{2}}: \text{figure } F \rightarrow \text{figure } F'$
 \overrightarrow{OP} is opposite to \overrightarrow{OP}' .
 $OP' = |-\frac{1}{2}| \cdot OP = \frac{1}{2} \cdot OP$

If the scale factor in Example 3 was -1 instead of $-\frac{1}{2}$, the figure F' would be congruent to the figure F , and the transformation would be an isometry, equivalent to a half-turn. In general, however, as these examples illustrate, dilations do not preserve distance. Therefore a dilation is not an isometry (unless $k = 1$ or $k = -1$).

But a dilation always maps any geometric figure to a similar figure. In the examples above, $\triangle ABC \sim \triangle A'B'C'$, $\triangle RST \sim \triangle R'S'T'$ and the figure F is similar to the figure F' . For this reason, a dilation is an example of a **similarity mapping**.
